Freehand endoscopic ultrasound-guided transrectal drainage of diverticulitis-associated abscess with electrocautery-enhanced lumen-apposing metal stent under spinal anesthesia

► Fig. 1 Computed tomography scan showing complicated diverticulitis Hinchey II with an abscess (red arrow).

Complicated diverticulitis occurs in 12% of all diverticulitis cases [1]. Radiological drainage is the first-line therapy in cases of large diverticulitis-associated abscess [2]. However, the pelvic location renders the radiological access challenging. Lower endoscopic ultrasound (EUS)-guided drainage, using an electrocautery-enhanced lumen-apposing metal stent (LAMS), is a feasible and safe alternative method for drainage of pelvic collections [3–5]. We present a case of a diverticulitis-associated abscess successfully treated using EUS-guided LAMS.

A 57-year-old man presented to the emergency room with abdominal pain and fever. His medical history revealed chronic obstructive pulmonary disease Gold IV. On admission, computed tomography (CT) scan showed a complicated acute diverticulitis Hinchey II with a pelvic abscess of 5 cm (▶ Fig. 1). The pelvic location of the abscess did not allow for radiological drainage and general anesthesia was contraindicated due to the patient's pulmonary disease. EUS-guided drainage of the pelvic abscess was performed under spinal anesthesia (▶ Video 1).

The diverticulitis-associated abscess was punctured freehand (► Fig. 2 a) using the electrocautery-enhanced LAMS (10 × 10 mm; pure cut mode, effect 4). After

deployment of the proximal flange (**Fig.2b**), a 0.035-inch guidewire was introduced through the LAMS into the abscess (**Fig.2c**). Then, the LAMS was deployed to drain the abscess into the lumen of the colon. Finally a double-pigtail stent was inserted through the LAMS to avoid LAMS obstruction (**Fig.2d**). No adverse events were reported.

Follow-up CT scan 2 weeks later showed complete resolution of the abscess. The LAMS was removed and the residual fistula was closed using clips. Follow-up CT scan and endoscopy at 2 months showed complete resolution of the abscess without fistula.

This case highlights the advantage of LAMS for drainage of a diverticulitis-associated abscess and its successful outcome without recurrence. Moreover, in patients with contraindication for general anesthesia, this procedure can be performed under spinal anesthesia. Prospective studies are needed to determine the role of EUS-guided drainage of diverticulitisassociated abscess using LAMS.
