## Abstract

**Objective** The present study has been designed to evaluate urinary nephryn that best predicts the occurrence of renal dysfunction in type 2 diabetes mellitus patients and its correlation with clinical parameters of nephropathy.

**Materials and Methods** A total of 80 type 2 diabetes mellitus and 40 age- and gender-matched healthy controls were recruited. Biochemical and clinical parameters were analyzed in all the study participants. Analysis of variance was performed to compare the differences between the groups. Pearson's correlation analysis was used to analyze the association of nephryn with clinical parameters of nephropathy. Receiver operating characteristic curves were constructed to study the diagnostic accuracy of markers to identify diabetic nephropathy.

**Results** The levels of nephryn were significantly elevated in both groups of type 2 diabetes mellitus patients when compared with healthy individuals ( $p = 0.0001$ ). The urinary nephryn was positively correlated with hemoglobin A1c and urinary albumin creatinine ratio ( $r = 0.520, 0.657, p < 0.0001$ ) and negatively correlated with estimated glomerular filtration rate ( $r = -0.539, p < 0.0001$ ). The diagnostic sensitivity and specificity of nephryn for nephropathy were 100 and 88%, respectively, and urinary albumin creatinine ratio was 43 and 76%, respectively.

**Conclusion** The study findings suggest that nephryn levels are strongly and positively associated with nephropathy in type 2 diabetes mellitus patients and it has a greater potential to be an early predictable marker of nephropathy than urinary albumin creatinine ratio.

## Introduction

Type 2 diabetes mellitus (T2DM) caused by hyperglycemia due to defect in insulin secretion from the  $\beta$  cells of pancreas and inactivation of insulin leads to insulin resistance.<sup>1</sup> T2DM

is one of the leading disorders in the world, where 415 million people were affected by the year 2015 and it is estimated to reach 650 million by 2030; in the Indian scenario 65 million were affected by the year 2013 and it is estimated to reach 103 million by the year 2030.<sup>2,3</sup>

T2DM leads to many micro- and macrovascular complications, this in turn affect many organs like the kidney, retina of the eye, brain, lungs, and heart, etc. and most of the diabetic people are affected with nephropathy. Diabetic nephropathy (DN) is the major microvascular complication in patients with T2DM due to hyperglycemia in the blood and hypoglycemia in the skeletal muscles leading to excess mobilization of lipids and proteins resulting in the production of reactive oxygen species and reduced antioxidants.<sup>4–6</sup> Currently, urinary albumin is used for the diagnosis of nephropathy in patients with T2DM. However, some of the recent researchers reported that microalbuminuria is not a gold standard, sensitive and specific, biomarker for diagnosis of nephropathy in patients with T2DM, because it also elevates in other disorders like obesity, hypertension, different types of kidney problems, etc. In addition to that some of the patients diagnosed with microalbuminuric stage are directly converting into normoalbuminuric stage due to treatment modalities.<sup>7–9</sup>

Along with that some of the recent studies found podocyte proteins to play an important role in the early prediction and progression of nephropathy, as such urinary nephrin is the one of the anchoring proteins of foot process of the podocytes in the kidney, urinary excretion nephrin levels are used for early detection of nephropathy in patients with T2DM. Nephrin is the transmembrane protein of the immunoglobulin super family and also it is a very essential component of slit diaphragm between the foot processes of the podocytes in the kidney.<sup>10</sup> The physiological action of nephrin is to maintain the size selectivity of the slit diaphragm and form a network of interdigitating foot processes of the podocytes in the kidney to prevent leaking of proteins.<sup>11</sup> Dysregulation of nephrin due to hyperglycemia in podocytes lead to nephrinuria particularly in T2DM patients with normoalbuminuric patients, preceding microalbuminuria.<sup>12</sup> However, very few studies have been done on urinary nephrin and also examined the relationship between urinary nephrin, hemoglobin A1c (HbA1C), urinary albumin, and estimated glomerular filtration rate (eGFR) in South Indian population and a study is required to evaluate sensitive and specific biomarker (urinary albumin and nephrin) for early detection of nephropathy in T2DM patients. Hence, in the present study we aimed to investigate the levels of urinary nephrin and correlate with urinary albumin and eGFR to predict early onset and progression of nephropathy in T2DM.

## Materials and Methods

This is a case–control study conducted in Basaveshwara Institute of Medical Sciences and Research Centre, Chitradurga, Karnataka, India, and Arupadai Veedu Medical College, Puducherry, India, from 2018 to 2021. A total 120 subjects with age group of 30 to 70 years were included in the study. Among these, 80 T2DM subjects were again divided into two groups: group 2: 40 T2DM patients with normoalbuminuria (duration of DM < 5 years, HbA1c: 6–7.5%, and albumin creatinine ratio [ACR]: < 30 mg/dL); group 3: 40 T2DM patients with microalbuminuria (duration of DM 5–10 years, HbA1c: 7.6–10.5%, and ACR: 30–299 mg/dL) (– Fig. 1). Additionally, we recruited

**Fig. 1** Selection of study subjects.

age- and gender-matched healthy controls considered as group 1 ( $n = 40$ ). All the T2DM subjects included in the study were diagnosed with different stages of nephropathy according to the American Diabetic Association criteria and Kidney Disease Improving Global Outcomes criteria<sup>13,14</sup>; patients smoking, alcoholism, liver diseases, hypertension, cardiovascular, cerebrovascular, thyroid, peripheral vascular diseases, and those in treatment on thiazolidine and anti-inflammatory were excluded from the study.

Seven milliliters of fasting (overnight 8–12 hours) venous blood sample and 3 mL of postprandial blood sample were collected from all the subjects after obtaining informed consent from. Two milliliters of blood sample was transferred into tube containing anticoagulant sodium fluoride, 2 mL transferred into tube containing anticoagulant ethylenediaminetetraacetic acid, and remaining 3 mL transferred into plain tube. Anticoagulant tubes were separated immediately and plain tube was allowed to rest for 10 minutes at room temperature for clotting. All the samples were centrifuged at 3,000 revolutions per minute (RPM) for 10 minutes, after centrifugation separated samples (plasma and serum) were transferred into properly labeled aliquots and stored at deepfreeze at  $-80^{\circ}\text{C}$  until biochemical analysis was done. Along with the blood sample urine sample was also collected from all the subjects, centrifuged at 3,000 RPM for 10 minutes, and after centrifugation of urine sample, 1 mL was separated into labeled aliquots, stored at deepfreeze at  $-50^{\circ}\text{C}$  and the remaining urine sample was immediately processed for urinary albumin and creatinine.

Plasma fasting blood sugar (FBS), postprandial blood sugar (PPBS), glycosylated HbA1c, serum urea, and creatinine were analyzed by using laboratory standard methods, eGFR was calculated by using Chronic Kidney Disease-Epidemiology Collaboration formula, urinary ACR was analyzed by using immunoturbidimetric method, and urinary nephrin was analyzed by using enzyme-linked immunosorbent assay.

## Statistical Analysis

The data were statistically analyzed by using Microsoft Excel spreadsheets, IBM Statistical Package for the Social Sciences (SPSS) Version 20.0, and Medcalc (Version 12.1, Ostend,

Belgium). First, the normality of the three groups of data distribution was tested using the Kolmogorov–Smirnov test. Continuous variables are expressed as mean ± standard deviation. Comparisons between the three groups were analyzed by using one-way analysis of variance (ANOVA). Pearson’s correlation analysis was done to test the correlation of urinary nephryn with other biochemical parameters. Receiver operating characteristic (ROC) curves were constructed to study the diagnostic accuracy of the markers to identify DN in the normoalbuminuric group when compared with healthy controls. A cutoff value with the best combination of sensitivity and specificity was determined from the ROC curve. Marker positivity in the groups studied were calculated based on values above the upper limit of the 75% confidence intervals of the median values of the markers and the ROC-derived cutoff values. A *p*-value of less than 0.05 was considered as statistically significant.

**Results**

► **Table 1** shows the plasma FBS, plasma PPBS, serum urea, serum creatinine, HbA1c, comparison of the routine biochemical parameters, and urinary biomarkers across the study groups. There is statistically significant elevation of plasma FBS, PPBS, HbA1c, serum urea, creatinine, urinary ACR, and nephryn in patients with T2DM compared with healthy controls, respectively, *p*-value of 0.0001.

► **Table 2** shows the comparison of the routine biochemical parameters and urinary biomarkers across the study groups by one-way ANOVA. There is statistically significant elevation of plasma FBS, PPBS, HbA1c, serum urea, creatinine, urinary ACR, and nephryn in the two groups of T2DM

subjects compared with healthy controls, respectively, *p*-value of 0.0001. It was also observed that T2DM subjects with microalbuminuria have high level of urinary nephryn then T2DM subjects with normoalbuminuria, respectively, *p*-value of 0.0001, which shows statistically highly significant relation.

► **Table 3** illustrates significantly increased levels of urinary nephryn along with increasing age in T2DM patients, respectively (*p* < 0.001).

► **Table 4** shows the correlation of urinary nephryn with other routine biochemical parameters of the subjects by using Pearson’s correlation analysis. We observed that urinary nephryn was positively significantly correlated with HbA1c and urinary ACR (*r* = 0.520, 0.657, respectively, *p* = 0.0001) and negatively correlated with eGFR (*r* = -0.539, respectively, *p* < 0.0001).

► **Fig. 2** shows the graphical representation of urinary nephryn distribution in all the three groups of study subjects. Significantly elevated level of urinary nephryn in T2DM subjects with normoalbuminuria and microalbuminuria was observed then in healthy controls.

► **Fig. 3** shows the distribution of urinary ACR levels in different groups of study subjects. T2DM subjects with microalbuminuria have significantly increased levels of urinary albumin when compared with T2DM subjects with normoalbuminuria and healthy controls.

► **Fig. 4** shows eGFR levels in the two groups of T2DM subjects and healthy controls and was compared between groups. Significantly decreased eGFR levels were observed in T2DM subjects with microalbuminuria then in T2DM subjects with normoalbuminuria and healthy controls.

## Discussion

Diabetic kidney disease (DKD) is one of the major microvascular complications in patients with T2DM and nowadays more than 40% of the DKD patients progress to end-stage renal disease.<sup>15</sup> In this condition damage of glomerular filtration barrier and tripartite system have fenestrated endothelial cells of glomerular basement membrane (GBM) and podocytes of kidney. The physiological action of these barriers is selective, filtration of water and solutes, and impermeable to leaking of macromolecules like proteins.<sup>16,17</sup> In T2DM patients, hyperglycemia in the blood and hypoglycemia in tissues trigger lipolysis and proteolysis resulting in the production of reactive oxygen species and

advanced glycation end products. These will bind to the advanced glycation end product receptors and trigger downstream signaling facilitating generation of free radicals, activating inflammatory cells, increasing synthesis of angiotensin II, and production of growth factors like vascular endothelial growth factors and transforming growth factor beta, finally leading to proteinuria.<sup>18,19</sup>

Urinary albumin estimation is used for testing the functional capacity of kidney, when patients show less than 30 mg/dL of albumin it is called normoalbuminuria, 30 to 299 mg/dL of albumin is microalbuminuria, and more than 300 mg/dL is macroalbuminuria, it depends on the duration of diabetes and further determined by eGFR.<sup>20</sup> Some of the recent studies reported that urinary microalbuminuria is not a

**Fig. 2** Distribution of urinary nephrin levels in three groups of study subjects.

**Fig. 3** Distribution of urinary albumin creatinine ratio (ACR) levels among the study subjects.

**Fig. 4** Distribution of estimated glomerular filtration rate (eGFR) levels among the study subjects.

sensitive and specific biomarker for detection of nephropathy in T2DM patients because it has low sensitivity and larger variability. Our study has shown statistically significant elevation of urinary ACR levels in T2DM patients with microalbuminuria when compared with T2DM patients with normoalbuminuria and healthy controls, *p*-value less than 0.0001 (► **Table 2**). However, earlier studies have reported that mean arterial blood pressure, plasma concentration of FBSs, HbA1c, aldosterone, atrial natriuretic peptide, vasopressin, and angiotensin II are also risk factors for proteinuria. Additionally, recent studies revealed that T2DM patients with microalbuminuria reverted to normoalbuminuria.<sup>21–23</sup>

If DN can be detected before the appearance of microalbuminuria, early intervention can be started to halt or reverse the process. Glomerular biomarker of renal injury is being studied as alternative markers for prediction of DN risk. Some of the recent studies found sensitive and specific biomarker for early detection of nephropathy in T2DM patients. Nephryn is a protein located in the podocytes of GBM of the kidney. Nephryn plays a vital role in podocytes and slit diaphragm to prevent excretion of protein in urine, but minimal structural alterations in podocytes lead to excretion of nephryn in urine prior to proteinuria. The studies are very limited and some of the studies found significantly elevated levels of urinary nephryn in T2DM and other studies reported the urinary nephryn levels were decreased in patient with T2DM.<sup>24–27</sup> The present study also analyzed urinary nephryn, and significantly elevated levels were observed in patients in both groups of T2DM when compared with healthy controls and we also found significantly increased levels of urinary nephryn in T2DM patients with normoalbuminuria when compared with healthy controls. Similarly, other studies also reported podocytes are present in the GBM of kidney and play a good role in maintaining glycocalyx of glomerulus and maintained the slit diaphragm size by specific proteins like nephryn and they also suggested that elevated levels of urinary nephryn were useful for early detection of nephropathy in T2DM patients.

We also found that urinary nephryn was positively correlated with blood sugars, glycosylated hemoglobin, urea, creatinine, and urinary albumin (► **Table 4**). Similarly, another recent study also reported that association of proximal tubule dysfunction with podocytes damage and dysfunction of proximal convoluted tubule proteins could be validated as an early diagnosis and progression of nephropathy in patients with T2DM.<sup>28,29</sup> Elevated levels of urinary nephryn in T2DM patients with normoalbuminuria stage and increased levels of more than two times in T2DM patients with microalbuminuria showed disease progression toward end-stage kidney disease.

The diagnostic utility of urinary ACR, eGFR, and urinary nephryn for the detection of early DN was compared between group 1 and group 2 by ROC curve analysis (► **Table 5**). Among these urinary ACR and eGFR there was no significant area under the curve (AUC), with sensitivity ranging from 43.33 to 46.67 and specificity 76.67 to 73.33, respectively, *p*-values 0.68 and 0.61 and the urinary nephryn showed a

**Table 5** ROC curve analysis of urinary ACR, eGFR, and urinary nephrin

Parameter	AUC	95% CI for AUC	Sensitivity (%) 95% CI	Specificity (%) 95% CI	p-Value
Urinary ACR (mg/dL)	0.532	0.398–0.662	43.33	76.67	0.683 <sup>a</sup>
eGFR (mL/min)	0.538	0.405–0.668	46.67	73.33	0.616 <sup>a</sup>
Urinary nephrin (ng/mL)	0.993	0.928–1.000	100.00	93.33	0.0001 <sup>b</sup>

Abbreviations: ACR, albumin creatinine ratio; AUC, area under the curve; CI, confidence Interval; eGFR, estimated glomerular filtration rate; ROC, receiver operating characteristic.

<sup>a</sup>Not significant.

<sup>b</sup>Highly significant.

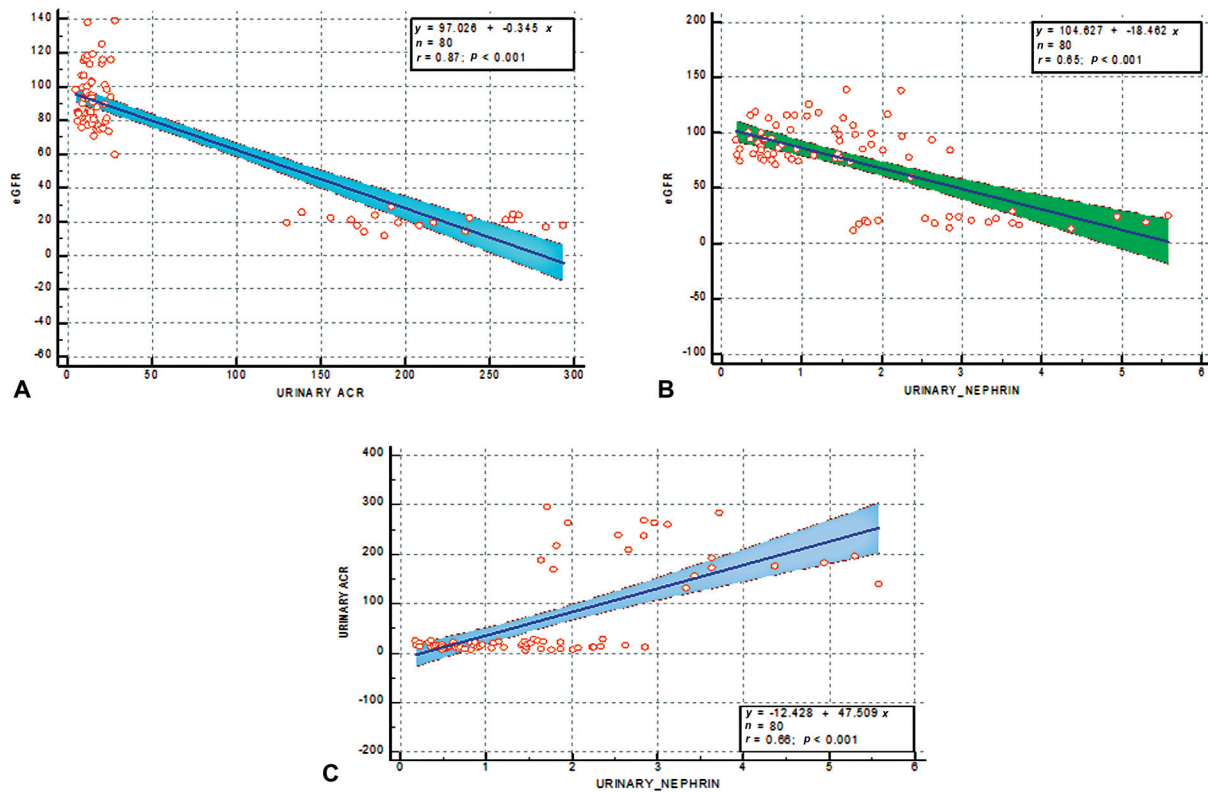

statistically significant AUC with sensitivity ranging from 100% and specificity from 93%, respectively, while *p*-value is less than 0.0001 (→ **Fig. 5**).

Univariate linear regression analysis was done by using eGFR as dependent variable and urinary ACR and urinary nephrin as independent variables and showed a significant inverse association. Along with that we also analyzed urinary

ACR as dependent variable and urinary nephrin as the independent variable and showed a direct association. The scatter plots showed a relationship between eGFR, urinary ACR, and urinary nephrin ( $r=0.87, 0.65, \text{ and } 0.66$ , respectively, *p*-values < 0.001) (→ **Fig. 6**). Hence, based on these findings urinary nephrin is identified as the best marker for diagnosis of DN then urinary ACR.

**Fig. 5** Receiver operating characteristic (ROC) curve analysis of estimated glomerular filtration rate (eGFR), urinary albumin creatinine ratio (ACR), and urinary nephrin.

**Fig. 6** Univariate linear regression analysis for early diagnosis of diabetic nephropathy.

## Conclusion

The outcome of this study showed that urinary nephrin might be a better marker than urinary ACR for predicting early onset of nephropathy in patients with T2DM, because urinary nephrin levels elevated and there was no change in urinary ACR levels in T2DM patients with normoalbuminuria.
