

A 23-year-old Caucasian woman underwent investigations for symptoms of epigastric pain and gastroesophageal reflux. She was treated with a proton pump inhibitor for a few months without any improvement in symptoms. Abdominal computed tomography and endoscopic ultrasound examination revealed a paraduodenal cystic lesion on the antimesenteric side of the second part of the duodenum. This lesion was echo-poor, was more than 6 cm in length, and was composed of multiple layers similar to those of the intestinal wall. The diagnosis was a duodenal duplication. Examination with a side-viewing Olympus TJF-160 duodenoscope revealed a soft and depressible mass (Figure 1). An incision was made with a needle-knife papillotome (Micro-knife XL; Boston Scientific Microvasive, Spencer, Indiana, USA) on the proximal, dependent portion of the cyst. The cyst was cannulated with a sphincterotome (Cotton Cannulotome II PC Double Lumen; Wilson-Cook Medical, Winston-Salem, North Carolina, USA). The incision was extended until an opening of 1.5 cm was obtained. One month later, a second endoscopy was performed and the duplication cavity was found to be totally collapsed. The previous incision was now about 2 cm long and was extended for another 1 cm (Figure 2). One month after discharge, the patient was well and symptom-free.

Duodenal duplication is rarely diagnosed in adults. The most common clinical manifestations are intestinal occlusion, pancreatitis, perforation, or bleeding but symptoms can also be nonspecific, as in our patient [1]. Traditionally, duodenal duplication has been managed surgically and complete resection is the classic treatment. Only a few cases of endoscopic treatment of duodenal duplication have been reported [1–4]. Duodenal duplications are benign lesions, although two cases of malignant transformation have been reported in the literature, probably related to the presence of ectopic tissue inside the cyst, which was not found in

our case [5,6]. In conclusion, endoscopic treatment of duodenal duplication is an effective procedure which results in rapid relief of symptoms and avoids the morbidity associated with a laparotomy.
