Abstract A simple method has been developed for the synthesis of 3-(2-oxo-2-phenylethylidene)-3,4-dihydroquinoxalin-2(1H)-one and 3-aryl-quinoxalin-2(1H)-one derivatives through C–H activation of quinoxalin-2(1H)-ones by peroxides and iodide. In this protocol, the peroxide (TBPB) serves as both the radical initiator and aryl source, realizing arylation of quinoxalin-2(1H)-one in a one-step reaction. The methodology has the advantages of being a metal-free strategy and having broad functional group tolerance.

Key words C–H activation, iodide/peroxide system, metal-free, quinoxalin-2(1H)-one, radical process

Quinoxalin-2(1H)-one scaffolds exist in many natural products. Due to the significant biological activities and pharmaceutical properties of this structure, such as anti-tumor,¹ ALR2 inhibition,² antibiotic,³ analgesic,⁴ antimicrobial,⁵ and aldose reductase inhibition activities (Figure 1),⁶ a range of 3-functionalized quinoxalin-2(1H)-ones has been synthesized, with approaches including arylation,⁷ alkylation,⁸ etherification,⁹ amidation,¹⁰ amination,¹¹ cyanation,¹² phosphonation,¹³ and trifluoromethylation (Scheme 1).¹⁴

Activation of C–H bonds has recently emerged as a powerful method for the construction of C–C bonds.^{15,16} Furthermore, radical addition is a powerful method to form C–C bonds,¹⁷ with the iodide/TBHP system being considered as a dominant protocol in the radical field to achieve C–H bond activation and construction of heterocyclic rings.^{18,19}

Scheme 1 Synthesis of 3-functionalized quinoxalin-2(1H)-one derivatives

Typical approaches for synthesizing 3-(2-oxo-2-phenylethylidene)-3,4-dihydroquinoxalin-2(1*H*)-ones involve reaction of aroyl- and heteroarylpyruvic acid or ester derivatives with *N*-phenyl-*o*-phenylenediamine (Scheme 2).^{20,21}

Scheme 2 Synthesis of 3-acetylquinoxalin-2(1*H*)-one derivatives

As for the synthesis of diverse 3-aryl-quinoxalin-2(1*H*)-ones, there were two main approaches. One strategy to construct the heterocyclic ring involves two-step acylation of benzene-1,2-diamines with arylglyoxylic acids, followed by subsequent cyclization (Scheme 3, method 1).^{7a} Other methods involve direct functionalization. Paul reported the novel Pd(TFA)₂-catalyzed direct dehydrogenative cross-coupling of quinoxalin-2-ones with arenes for the construction of diverse 3-aryl quinoxalin-2-ones (Scheme 3, method 2).^{7b} Ramesh reported an oxidative cross-coupling of arylboronic acids with quinoxalin-2-ones using the readily available oxidant Mn(III) acetate dihydrate (Scheme 3, method 3).^{7c} Yin's group used diaryliodonium tetrafluoroborates at room temperature, with arylhydrazines as the arylating agent (Scheme 3, method 4).^{7d} Lee and co-workers reported iodosobenzene-promoted direct arylation with arylhydrazines as radical precursors (Scheme 3, method 5).^{7e} However, drawbacks such as the requirement for prefunctionalized substrates, multistep protocols, low atom economy, use of transition-metal catalysts and strong base in these protocols have limited their general application and development. Metal-free systems have replaced tradition metal systems, and iodide or hypervalent iodine possess advantages such as ease of handling, strong electrophilicity, commercial availability, and low toxicity.²²

Scheme 3 Synthetic approaches to 3-arylquinoxalin-2(1*H*)-ones

The I₂/TBHP system is a central reagent combination in the radical field.^{23,24} It has been shown that *tert*-butyl peroxybenzoate (TBPB) is an efficient and highly chemoselective benzoylating reagent.^{25,26} In this area, we first disclosed that TBPB could translate into aryl radicals, triggering subsequent reactions, providing a novel method for the introduction of an aryl group.

Herein, we disclose a simple method to synthesize 3-functionalized quinoxalin-2(1*H*)-ones. In the first part, we present a *n*-Bu₄Ni-catalyzed radical oxidative coupling of acetophenone and quinoxalin-2(1*H*)-ones using TBHP as oxidant to access 3-(2-oxo-2-phenylethylidene)-3,4-dihydroquinoxalin-2(1*H*)-ones. In the second part, the direct arylation of quinoxalin-2(1*H*)-ones is disclosed. Therein, TBPB is used both as reagent to generate aryl radical and as free radical initiator, while I₂ is used as catalyst (Scheme 4).

Scheme 4 Studies reported herein

Initially, we chose 1-methylquinoxalin-2-(1*H*)-one (**1a**) and acetophenone (**2a**) as model substrates. The reaction was carried out using 20 mol% of TBAI, 5 equivalents of *tert*-butyl hydroperoxide (TBHP, 70% solution in water) in DCE at 100 °C. Under these conditions, the desired product **3a** was obtained in 32% yield (Table 1, entry 4).

Next, we studied a series of iodides and found that using TBAI as catalyst gave higher yields (Table 1, entries 1–7). Then, several oxidants were investigated, such as dibenzoyl peroxide (BPO), *tert*-butyl peroxybenzoate (TBPB), dibutyl peroxide, K₂S₂O₈, and DDQ, but the reaction with TBHP still resulted in the best result (Table 1, entries 8–11). When we increased the amount of (**2a**) from 2 equivalents to 4 equivalents and decreased the amount of TBHP from 5 equivalents to 3 equivalents, the yield of target product was increased to 86% (Table 1, entries 12, 13). Finally, other solvents (DMSO, H₂O, 1,4-dioxane, toluene) were studied instead, but unfortunately no improvement in yield was observed (Table 1, entries 14–17). Ultimately, we chose (**1a**, 0.3 mmol), (**2a**, 4.0 equiv.), TBAI (20 mol%), and TBHP (3.0 equiv.) in DCE (2 mL) at 100 °C for 48 hours as the optimal reaction conditions.

Unexpectedly, we observed a byproduct in a relatively low yield, with 3-arylquinoxalin-2(1*H*)-one **4a** being observed when BPO or TBPB were used as oxidant. It was observed that reaction with iodine showed a slightly higher yield (Table 2, entry 2). Subsequently, a variety of solvents

such as acetonitrile, 1,4-dioxane, and DMSO was investigated (Table 2, entries 6–8). Finally, we surveyed varying the effect of temperature (Table 2, entries 4, 5), but the reaction did not proceed well. In order to confirm the source of the aryl group, we conducted experiments without acetophenone. To our satisfaction, the yield of **4a** was increased from 34% to 61% (Table 2, entry 9). Finally, the number of equivalents of iodine and TBPB was investigated, and the yield was eventually improved to 95% (Table 2, entries 10–13). Considering the hazards associated with TBPB, 5 equivalents of TBPB were chosen as the preferred conditions. Thus, the optimized reaction conditions were chosen as TBPB (5 equiv.), I₂ (2 mol%) in DCE at 100 °C for 8 hours.

With the optimized conditions in hand, a range of quinoxalin-2(1H)-ones was investigated to give the corresponding derivatives **3** (Scheme 5). These *N*-substituted quinoxalin-2(1H)-one analogues showed good reactivities, giving the anticipated products **3aa–aj** in 32–93% yields.

In particular, an *N*-phenyl-substituted quinoxalin-2(1H)-one was well tolerated, giving the corresponding product **3aj** in 64% yield. Likewise, it was found that substrates with *N*-propyl, *N*-butyl and *N*-cyclohexylmethyl substitution provided the desired products (**3ag**, **3ae**, and **3af**) in good yields. Then, we explored substitution at R¹ and R² with R³ = CH₃ (Scheme 5). Electron-donating and electron-withdrawing groups provided the desired products in moderate to good yields (**3ak**, **3al**, and **3an**). Subsequently, we found that electron-withdrawing substituents (–F, –Br) had a positive effect compared to an electron-donating group (–CH₃). Furthermore, a substrate with an additional aromatic ring resulted a high yield of 73% (**3am**).

Finally, we studied the scope of acetophenones (Scheme 6). When the substrates possessed electron-donating groups, the yields were lower with a substituent at the *ortho* position than at the *para* position. In addition, *o*-hydroxyacetophenone also gave the desired product **3ba** in 57% yield. With electron-withdrawing groups present at the *ortho* or *para* positions, the corresponding products **3bb–bi** were obtained in 33–74% yields. The π -extended aromatic substrate provided the expected product **3bj** in a 78% yield.

Most of the substrates studied gave the expected products **4aa–ai** in moderate to excellent yields (Scheme 7). *N*-Substituted quinoxalin-2(1H)-ones containing *N*-ester, *N*-benzyl, *N*-benzene acetyl, *N*-propyl, and *N*-aryl substitu-

ents were all suitable for this reaction, providing the desired products in moderate to good yields. In addition, *N*-phenyl quinoxalinone gave the corresponding product **4af** in 94% yield. Finally, we explored substitutions at R¹ and R² with R³ = CH₃. An electron-withdrawing substituent (–Cl) had a positive effect compared to an electron-donating group (–CH₃). Appending an additional aromatic ring also led to **4ai** in 70% yield (Scheme 7).

Addition of a radical-trapping reagent such as 2,2,6,6-tetramethylpiperidine *N*-oxide (TEMPO) or BHT to the reaction suppressed the transformation, strongly indicating that the C–C bond formation is a radical-mediated process (Scheme 8).

On the basis of this result, a plausible reaction mechanism can be proposed (Scheme 9). Either the *tert*-butoxy radical or *tert*-butylhydroperoxy radical can remove a hydrogen atom from **2a** to form radical intermediate **5**. Addition of intermediate **5** to **1a** affords intermediate **6**. Then

intermediate **6** can undergo 1,2-H shift to form the more stable intermediate **7**. Finally, the final product **3a** is obtained by hydrogen-atom removal by a *tert*-butoxy radical.

Scheme 8 Experiments with added radical inhibitors

Scheme 9 Plausible reaction mechanism

For the TBPB reaction catalyzed by I_2 , the benzoyl radical releases carbon dioxide forming the phenyl radical under standard conditions. Addition of the phenyl radical to the carbon–nitrogen double bond affords radical intermediate **10**, which is further oxidized by the iodide cation to form nitrogen cation compound **11** that then undergoes 1,2-H shift to give **12**. Finally, the desired compound is obtained by hydrogen-atom removal to give **4a** (Scheme 10).

Scheme 10 Plausible reaction mechanism

In conclusion, we have developed a novel protocol for direct synthesis of 3-(2-oxo-2-phenylethylidene)-3,4-dihydroquinoxalin-2(1H)-ones. The iodide/peroxide system has

been shown to be a powerful combination to activate the C–H bond of quinoxalin-2(1H)-ones. This process exhibits good functional group tolerance with a broad substrate scope, resulting in acetylation of quinoxalin-2(1H)-ones and providing a new method for the introduction of an aryl group.
