

Take Two CO: Access to γ -Boryl Esters by Boration and Carbonylative Catenation of Styrenes in One Pot

Selected examples:

Proposed mechanism:

Significance: A copper-catalyzed carbonylative four-component coupling of olefins to access γ -boryl esters is disclosed. Two CO molecules act as the $-\text{CH}_2\text{CO}-$ source. The regio- and *syn*-selective borylcupration gives the products in high stereoselectivity.

Comment: Based on ^{13}C and ^2H NMR labeling experiments, the shown mechanism is proposed. Further synthetic transformations of the γ -boryl esters were performed to demonstrate the synthetic utility of this protocol.
